

Matter can be described by its **physical properties** (**properties** of matter which can be perceived or observed **without** changing the chemical identity of the sample):

Physical Property	Description
Shape	External form or appearance characteristic; the outline of an area or figure:
Density	Mass per unit volume of an object ( $D = M/V$ )
Solubility	Ability to dissolve
Odor	Fragrance
Melting point	Temperature at which it changes state from solid to liquid
Boiling point	Temperature at which a liquid boils and turns to vapor.
Color	Byproduct of the spectrum of light, as it is reflected or absorbed, as received by the human eye

Matter can also be described by its **chemical properties** (**properties** of matter that may only be observed and measured by performing a **chemical change** or **chemical** reaction):

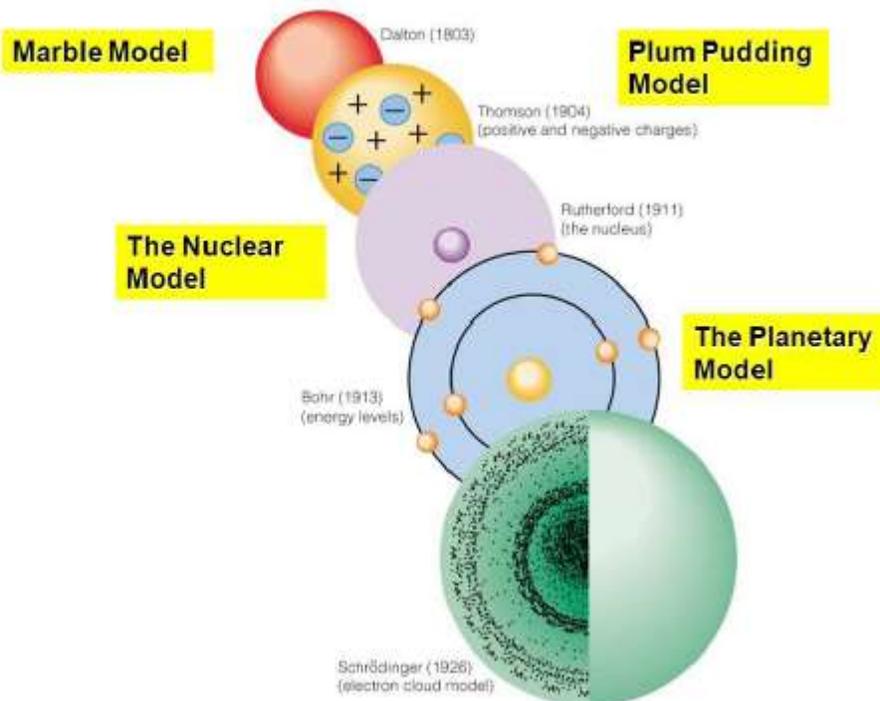

Chemical Property	Description
Acidity	The level of acid in substances
Basicity	<b>Condition of being a base</b>
Combustibility	Capable of catching fire and burning
Reactivity	The rate at which a chemical substance tends to undergo a chemical <b>reaction</b>

## CHANGES IN MATTER

Types of Changes	Description	Examples
<b>Physical</b>	Physical changes, the chemical composition of the substances does not change.	<ul style="list-style-type: none"> <li>• Energy stored in the Any phase change</li> <li>• Grinding something into powder</li> </ul>
<b>Chemical</b>	Different substances are formed	<ul style="list-style-type: none"> <li>• Iron rusting</li> <li>• Gasoline burning</li> </ul>
<b>Nuclear</b>	Energy stored in the nucleus of an atom.	<ul style="list-style-type: none"> <li>• Joining nuclei together (fusion)</li> <li>• Splitting nuclei (fission).</li> </ul>

# Unit 2 Review (Atoms and the Periodic Table)

## HISTORICAL DEVELOPMENT OF THE ATOM

## MODERN MODEL OF ATOM

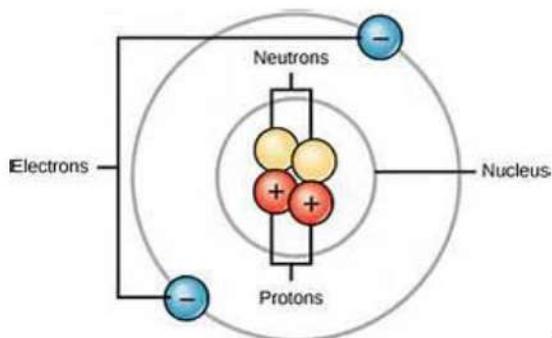

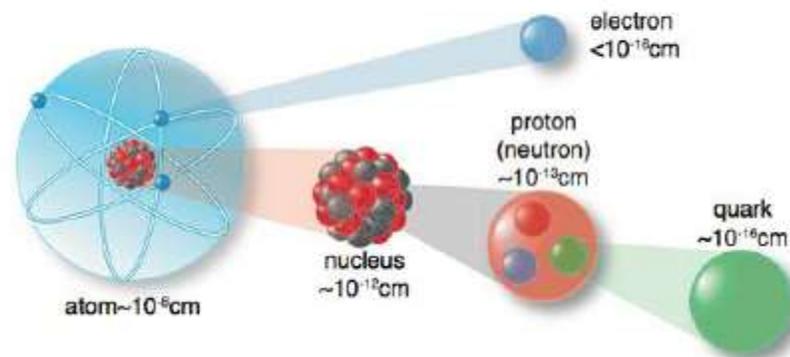

Image Source: voer.edu.vn

### **Matter can be classified as:**

- Elements
- Compounds
- Mixtures

The atoms of any **element** are alike but are different from atoms of other elements.

**Compounds** consist of **two or more elements** that are **chemically combined** in a fixed ratio.

**Mixtures** also consist of **two or more substances**, but the substances are **not chemically combined**.

Heterogeneous Mixture- A mixture in which substances are not evenly mixed

Homogeneous Mixture- A mixture in which two or more substances are mixed evenly on the atomic level but not bonded together

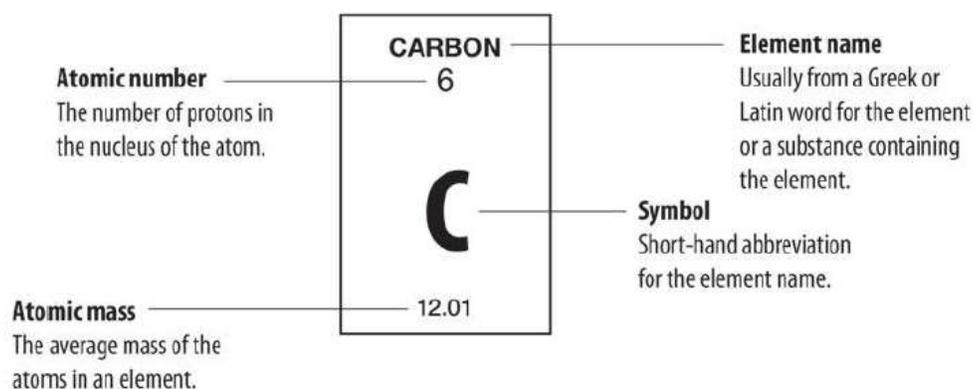

**How can you determine whether a substance is an element, compound or mixture?**

- An element contains just one type of atom
- A compound contains two or more types of atom joined together
- A mixture contains two or more different substances that are not joined together
- The different substances in a mixture can be elements or compounds

John Dalton, a scientist, is known for his "Atomic Theory". Here are Dalton's main conclusions which still hold true until today:

- Atoms can't be broken into smaller pieces. Atoms are indivisible.
- In any element, all the atoms are exactly alike.
- Atoms of different elements are different.
- Atoms of two or more elements can combine to form compounds
- Atoms of each element have a unique mass.
- The masses of the elements in a compound are always in a constant ratio

## Elements

*Image Source: Middle School Chemistry.com*

**Chemical symbols** are abbreviations used to represent over 100 known elements. Chemical symbols use one or two letters. The first letter is always capitalized and the second, if there is one, is always lowercase. Usually these are the first two letters of the element's name but this is not always possible, because it would sometimes cause the same letter(s) to be used more than once.

**Molecules**- a group of atoms bonded together, representing the smallest fundamental unit of a chemical compound that can take part in a chemical reaction (ex. Water has a molecular formula of H<sub>2</sub>O.)

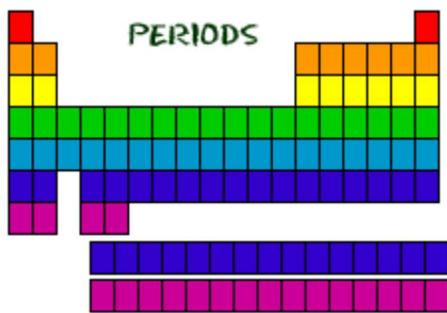

## ORGANIZATION OF PERIODIC TABLE

The Russian scientist Dmitri Mendeleev discovered a set of patterns in the properties of the elements. He noticed that a pattern of properties appeared when he arranged the elements in order of increasing atomic mass. The **atomic mass** of an element is the average mass of all the isotopes of that element. After protons were discovered, elements were **rearranged according to atomic number**.

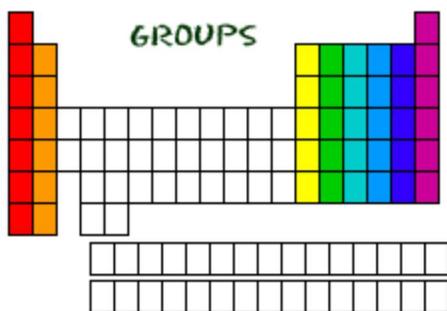

- The atomic number of an element is the number of protons in each atom of that element
- The elements in the periodic table are arranged by increasing atomic number
- The number of valence electrons increases from left to right across each period

**The Periodic Table:** *The **periodic table** is a chart of the elements arranged into rows (left to right) called **periods** and columns called **groups** (up and down) according to their physical and chemical properties. **Elements in each group have similar characteristics.***

All of the rows read left to right. Each row is called a **period**. All of the elements in a period have the same number of **atomic orbitals**. For example, every element in the top row (the first period) has one orbital for its **electrons**.

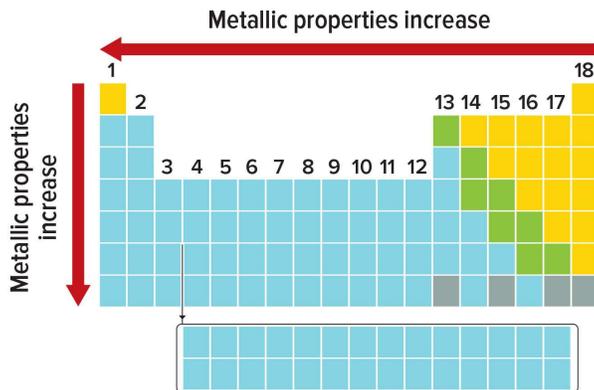

Each column is called a **group or family**. The elements in each group have the same number of electrons in the outer **orbital**. Those outer electrons are also called **valence electrons**. They are the electrons involved in chemical bonds with other elements.

The family name of a group is typically the name of the first element in the column. **Elements in each group have similar characteristics.**

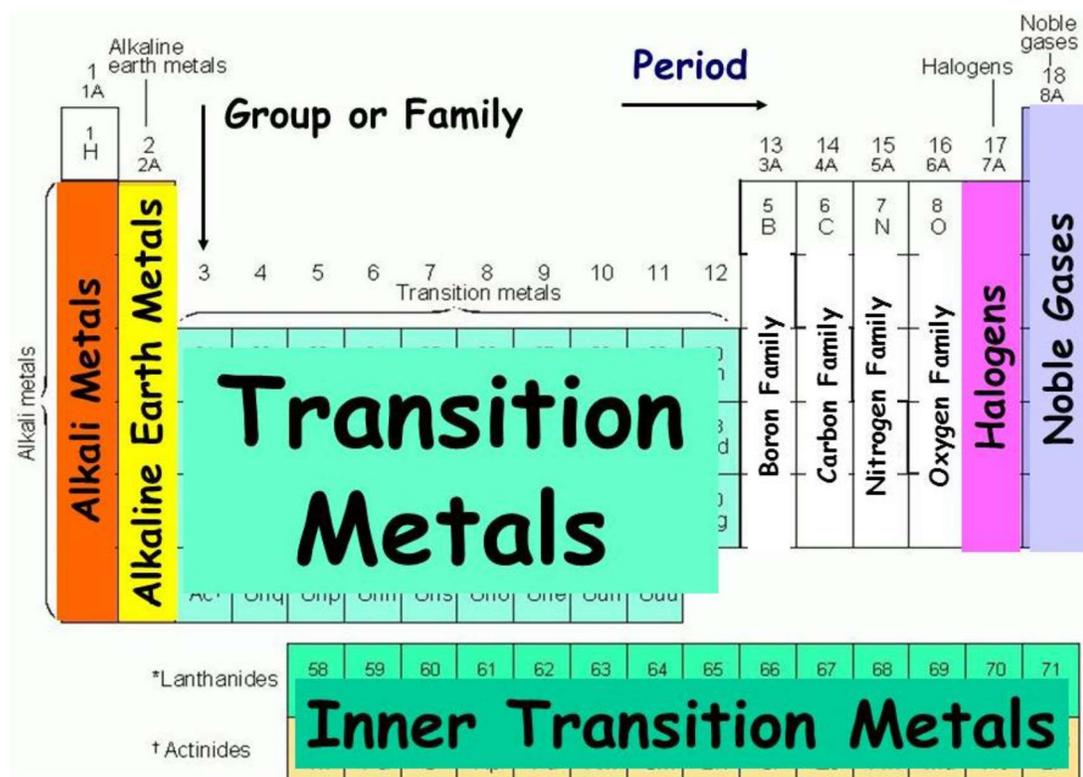

## Patterns in Properties of Metals

Recall that the properties of elements follow repeating patterns across the periods of the periodic table. In general, elements increase in metallic properties such as luster, malleability, and electrical conductivity from right to left across a period.

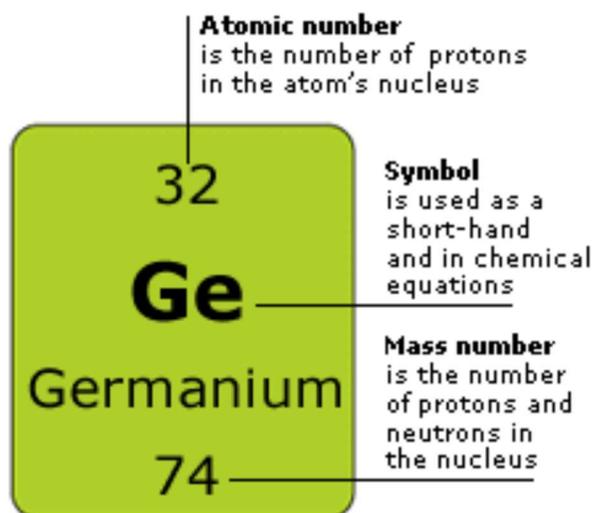

Each **element** is placed in a specific location because of its atomic structure. The periodic table has rows (left to right) and columns (up and down). Each row and column has specific characteristics. All of the rows read left to right.

Each row is called a **period**. All of the elements in a period have the same number of **atomic orbitals**. For example, every element in the top row (the first period) has one orbital for its **electrons**.

Hydrogen (H) and helium (He) are special elements. **Hydrogen** can have the electron traits of two groups: one and seven. **Helium** (He) is different from all of the other elements. It is very stable with only two electrons in its outer orbital (valence shell). Even though it only has two, it is still grouped with the **noble gases** that have eight electrons in their outermost orbitals. The noble gases and helium are all "happy," because their valence shell is full.

**Atomic Number = number of protons or number of electrons**

**Atomic Mass = Atomic Number/Number of Protons/Number of Electrons – Number of Neutrons**

Elements of the periodic table are grouped as metals, metalloids or semimetals, and nonmetals. The metalloids separate the metals and nonmetals on a periodic table. Also, many periodic table have a stair-step line on the table identifying the element groups. The line begins at boron (B) and extends down to polonium (Po). Elements to the left of the line are considered *metals*. Elements just to the right of the line exhibit properties of both metals and nonmetals and are termed *metalloids* or *semimetals*.

Elements to the far right of the periodic table are *nonmetals*. The exception is hydrogen (H), the first element on the periodic table. At ordinary temperatures and pressures, hydrogen behaves as a nonmetal.

Properties of Metals	Properties of Metalloids or Semimetals	Properties of Nonmetals
<ul style="list-style-type: none"> <li>usually solid at room temperature (mercury is an exception)</li> <li>high luster (shiny)</li> <li>metallic appearance</li> <li>good conductors of heat and electricity</li> <li>malleable (can be bent and pounded into thin sheets)</li> <li>ductile (can be drawn into wire)</li> </ul>	<ul style="list-style-type: none"> <li>dull or shiny</li> <li>usually conduct heat and electricity, though not as well as metals</li> <li>often make good semiconductors</li> <li>often ductile</li> <li>often malleable</li> </ul>	<ul style="list-style-type: none"> <li>dull appearance</li> <li>usually brittle</li> <li>poor conductors of heat and electricity</li> </ul>

Lanthanoid Series

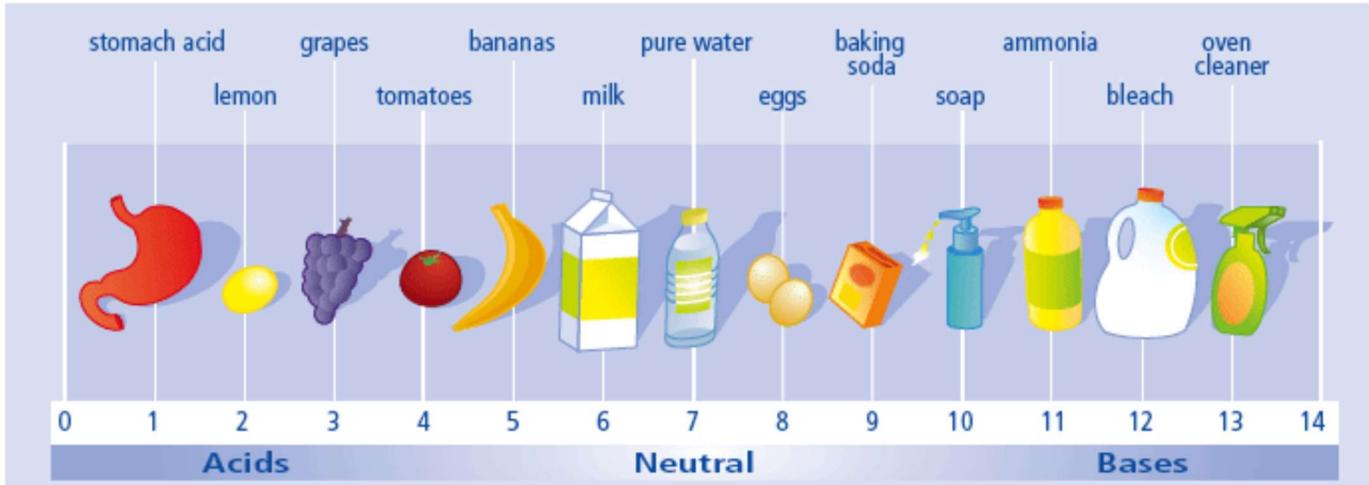

Actinoid Series

Compounds can be classified in several ways, including:

- acids, bases, salts
- inorganic and organic compounds.

### ACIDS AND BASES

**pH** is the **hydrogen ion concentration** in a water-based solution. The **pH scale** measures **how acidic or basic** a substance is. It ranges from 0 to 14. A pH of 7 is neutral. A pH less than 7 is **acidic**, and a pH greater than 7 is **basic**.

Acids	Bases
Less than 7 (pH scale)	More than 7 (pH scale)
Taste sour	Taste bitter and feel slippery
H <sup>+</sup> ions when dissolved in water	OH <sup>-</sup> ions when dissolved in water
Changes blue litmus paper red	Changes red litmus paper blue
